The Palladium-Catalyzed Trifluoromethylation of Aryl Chlorides

Eun Jin Cho, Todd D. Senecal, Tom Kinzel, Yong Zhang, Donald A. Watson,* Stephen L. Buchwald†

The trifluoromethyl group can dramatically influence the properties of organic molecules, thereby increasing their applicability as pharmaceuticals, agrochemicals, or building blocks for organic materials. Despite the importance of this substituent, no general method exists for its installment onto functionalized aromatic substrates. Current methods either require the use of harsh reaction conditions or suffer from a limited substrate scope. Here we report the palladium-catalyzed trifluoromethylation of aryl chlorides under mild conditions, allowing the transformation of a wide range of substrates, including heterocycles, in excellent yields. The process tolerates functional groups such as esters, amides, ethers, acetals, nitriles, and tertiary amines and, therefore, should be applicable to late-stage modifications of advanced intermediates. We have also prepared all the putative intermediates in the catalytic cycle and demonstrated their viability in the process.

he introduction of the strongly electron-withdrawing trifluoromethyl group into organic molecules can substantially alter their properties (such as lipophilicity, metabolic stability, and bioavailability) that affect the use of these molecules as pharmaceuticals and agrochemicals (*1*–*3*). Additionally, trifluoromethylated organic compounds find applications as materials such as liquid crystals (*2*). Despite the importance of this substituent, no general catalytic method exists for the introduction of the CF₃ group onto functionalized aromatic intermediates (*4*).

Structurally simple benzotrifluorides are accessible by radical chlorination of toluene derivatives and subsequent chlorine-fluorine exchange under harsh conditions (5). The replacement of an aromatic halide by a CF₃ group via coppermediated coupling proceeds under milder reaction conditions but is mainly limited to aryl iodides (6-16). A catalytic version of this process was recently reported, but only aryl iodides with electron-withdrawing substituents and some heterocycles are good substrates (17).

A palladium-catalyzed trifluoromethylation of aryl halides (Fig. 1) has the potential to overcome these limitations: The use of a trifluoromethyl

Department of Chemistry, Massachusetts Institute of Technology (MIT), Cambridge, MA 02139, USA.

*Present address: Department of Chemistry and Biochemistry, University of Delaware, Newark, DE 19716, USA. †To whom correspondence should be addressed. E-mail: sbuchwal@mit.edu source as a transmetalating agent obviates the need for harsh reaction conditions that are required to replace individual substituents on benzylic carbon atoms with fluorine. Additionally, because many known ligands promote oxidative addition, even into unactivated aryl chlorides at low temperatures, a wide substrate scope is possible.

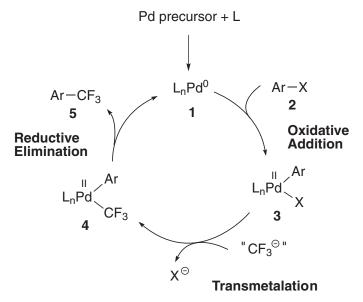

Mainly due to the high activation barrier for reductive elimination, the development of such a process has so far been unsuccessful. Several

no (18, 19) or only trace amounts (20) of the benzotrifluoride products 5, even after prolonged heating at 130°C. The chelating biphosphine ligands 1,2-Bis(diphenylphosphino)ethane (dppe) and 1,3-Bis(diphenylphosphino)propane (dppp) promote the reductive elimination of 4, only at 145°C, to give PhCF3 in 10 to 60% yield after 64 hours (19). On the other hand, the feasibility of fast Ar-CF₃ bond formation from a Pd(II) complex under mild conditions was demonstrated by Grushin and Marshall through quantitative conversion of the complex [XantphosPd(Ph)(CF₃)] to PhCF₃ upon heating to 80°C within 3 hours (21). However, the replacement of the Xantphos ligand in 3 with trifluoromethyl ions competes with transmetalation to 4, and consequently, no catalytic system with this system was reported (21, 22). Complexes 4 are typically prepared from

complexes (4) with bidentate ligands yield either

Complexes 4 are typically prepared from complexes 3, where X = Br or I, by treatment with TMSCF3 (TMS, trimethylsilyl) and a fluoride source such as CsF, thereby using the formation of a silicon-fluorine bond as driving force (18-20). The challenge of using trifluoromethylsilanes in the presence of fluoride originates in the fluoride-initiated self-decomposition of R_3SiCF_3 to give R_3SiF and difluorocarbene (23). In a catalytic setting, where elevated temperatures are presumably required to promote reductive elimination from 4

Fig. 1. Generalized catalytic cycle for aryl trifluoromethylation (L = ligand; Ar = aryl; X = Cl, Br, I, triflate).

to **5**, transmetalation must be substantially faster than this process.

The oxidation of Pd(II)-CF₃ complexes with a F⁺ reagent provides Pd(IV) complexes that readily reductively eliminate benzotrifluorides (20). The catalytic trifluoromethylation of arenes via C-H activation, oxidation of the Pd(II) intermediate with an electrophilic CF₃⁺ source, and final reductive elimination have recently been reported, but are limited to substrates with specific directing groups (24).

We report the development of a palladium-catalyzed procedure to transform aryl chlorides into their trifluoromethylated analogs using TESCF₃ (TES, triethylsilyl) and KF. High functional-group tolerance under relatively mild conditions is exhibited, and a wide range of substrates, including heteroaryl ones, can be efficiently converted to the desired products. Mechanistic studies suggest that the reaction proceeds via a classical Pd(0)-Pd(II) catalytic cycle, as shown in Fig. 1.

Ligand 6 (BrettPhos) (Fig. 2A) has successfully been employed in challenging amination and fluorination cross-coupling reactions (25, 26). We prepared the oxidative-addition complex 8 and examined numerous trifluoromethyl sources to identify conditions under which both transmetalation and reductive elimination would proceed (table S1) (27). Although most reagents failed to produce a product, the mixture of TESCF₃ and CsF in tetrahydrofuran (THF) at 60°C provided 9 in a promising yield of 28% (Fig. 2B). This result confirms that 6 does indeed promote reductive elimination to form Ar-CF₃ bonds and provides a starting point for the development of a catalytic procedure.

With 3 mole percent (mol %) [(allyl)PdCl]₂ and 12 mol % of ligand **6**, benzotrifluoride **9** was formed in 7% yield from aryl chloride **10** with TESCF₃ and CsF at 110°C. We next investigated several combinations of TMSCF₃ or TESCF₃ with simple fluoride salts and found that the highest yield was obtained using TESCF₃ with KF, demonstrating that the catalytic formation of **9** from **10** is possible with these transmetalating agents (Fig. 2C). Full conversion of **10** was achieved by switching the solvent to dioxane and performing the reaction at 120°C, providing **9** in 80% yield.

We studied the performance of other ligands under these conditions and found that **6** was the best ligand for this transformation (table S2). Most other monodentate biaryl phosphine ligands gave lower, but still observable, amounts between 5 and 20% of product **9**. No reaction occurred, however, when Xantphos was used.

The palladium-catalyzed process expands the scope to aryl chlorides and exhibits compatibility with a wide range of functional groups (Fig. 3). Both electron-poor and electron-rich aryl chlorides are suitable substrates and provide the trifluoromethylated products in good yields. More importantly, heteroaromatic substrates such as indoles, carbazoles, quinolines, and benzofuranes can be efficiently transformed into their trifluoromethylated analogs. When using ligand 6, we found that

Fig. 3. Scope of the palladium-catalyzed trifluoromethylation of aryl and heteroaryl chlorides. Isolated yields are based on an average of at least two runs. Minor amounts (2 to 5%) of reduced starting material (Ar-H) were usually observed. In a typical experiment, a solution of the palladium source and ligand 6 or 7 in dioxane was added to spray-dried KF and the aryl chloride. After addition of TESCF3, the reaction was stirred at 120 to 140°C for 6 to 20 hours. Because KF is hygroscopic, all reactions were set up in a nitrogen-filled glovebox to prevent the hydrolysis of TESCF3 in the course of the reaction. Et, ethyl; Hex, hexyl; Ph, phenyl.

^{* 120 °}C; † the compound could not be separated from the reduced Ar-H product. The given yield was estimated by gas chromatography; ‡ 2 mol% [(allyl)PdCl]₂, 6 mol% **6**; § 8 mol% Pd(dba)₂, 12 mol% **6**; $^{\parallel}$ 12 mol% **6**

ortho-substituted substrates gave the corresponding products in low yields only. Switching to the less bulky ligand RuPhos (7) (Fig. 2A) (28) provided the desired ortho-substituted products 11r-v in excellent yields. Scale-up proved to be straightforward; products 11j and 11b were prepared on 2- and 5-mmol scales, respectively, in the same yields as those reported for the 1-mmol-scale reactions.

Esters, acetals, amides, nitriles, ethers, dial-kylamines, and a number of heteroaromatic substituents are tolerated. However, substrates bearing aldehydes or ketones are not suitable. Furthermore, substrates cannot contain unprotected OH or NH groups, presumably because of protonation of the CF₃ anion to form fluoroform, reaction at the silicon center of TESCF₃, and/or competing coordination to the palladium center.

To gain insight into the reaction mechanism, we prepared the presumptive Pd-CF₃ intermediates **13** and studied their reductive elimination to yield benzotrifluoride products. Treatment of complexes **12** with TESCF₃/CsF at room temperature in THF allowed the isolation of [6•Pd(Ar)(CF₃)] complexes **13** (Fig. 4A). The compounds exhibit a characteristic quartet in the ³¹P-nuclear magnetic resonance (NMR) spectrum and a doublet in the ¹⁹F-NMR spectrum with a coupling constant of ~45 Hz. The Pd atom in the crystal structures of **13a** (fig. S1) and **13b** (Fig. 4B) is coordinated by the upper-ring methoxy group of the ligand **6** and not by the ipso carbon atom of the lower aromatic ring.

We studied the reductive elimination of complexes 13 in dioxane at 80°C via ¹⁹F-NMR and found first-order decay to give benzotrifluorides 14 in nearly quantitative yield. The rate constants for both the decomposition of 13a and

13b are almost identical (Fig. 4A and fig. S2 and S4). This surprising result is paralleled by density functional theory calculations that predict an activation energy of \sim 22 kcal mol $^{-1}$ for both complexes (29, 30). In comparison to the ground states, the calculated Pd-CF $_3$ distance in the transition states is substantially elongated, whereas the distance between the Pd atom and the aryl ring remains essentially unchanged, suggesting that the main contribution to the activation energy is the breaking of the strong Pd-CF $_3$ bond. Because the strength of this bond is only minimally influenced by the substituent on the aryl ring, similar rate constants are observed.

When complex 13a was heated in the presence of excess methyl 4-chlorobenzoate, the oxidative-addition complex 12a was formed in addition to product 14a, thus closing the catalytic cycle. The yield and rate of benzotrifluoride formation were identical in the presence or absence of aryl chloride (fig. S3), which implies that reductive elimination affords a Pd(0) species that then undergoes oxidative addition to form 12a. Therefore, we believe that these reactions proceed via a classical Pd(0)/Pd(II) catalytic cycle, as proposed in Fig. 1.

In preliminary experiments, we have demonstrated that this process is applicable, in somewhat lower yields, to aryl bromides and aryl triflates. We are currently seeking to develop a better understanding of the overall reaction mechanism, as well as to render this process more generally useful and practical. We hope to accomplish this by broadening its substrate scope, lowering the quantity of catalyst necessary, developing milder reaction conditions, and using less expensive and more environmentally friendly trifluoromethylating agents.

The Palladium-Catalyzed Trifluoromethylation of Aryl Chlorides

Eun Jin Cho, Todd D. Senecal, Tom Kinzel, Yong Zhang, Donald A. Watson and Stephen L. Buchwald

Science **328** (5986), 1679-1681. DOI: 10.1126/science.1190524

Three Fluorines at Once

The trifluoromethyl (CF₃) group is playing an increasingly important role in the design of pharmaceutical and agrochemical compounds. CF₃ is a powerful attractor of electron density within a given molecular framework, and recently fluorine-hydrocarbon interactions have emerged as a distinct complement to the more traditional hydrophilic/hydrophobic interplay that governs docking between small molecules and proteins. **Cho et al.** (p. 1679) now present an efficient method for appending CF₃ groups to a broad range of aryl substrates. A carefully optimized palladium catalyst was able to speed up a critical elimination step that has plagued previous efforts to realize a general solution to this synthetic challenge.
